## Fluorescence Spectra and Time-Resolved Fluorescence Decays

Emission spectra were recorded on a Spex Fluorolog 3 equipped with a xenon lamp and a NIR sensitive photomultiplier tube (R2658). Due to the low fluorescence quantum yield for the cyclic structures, a small amount of highly fluorescent impurities caused distortion of the emission spectra. The compounds $\mathbf{1 a - 3}$ and $\mathbf{1 a}$ were hence measured with excitation at longer wavelengths than the impurity absorption. Time-resolved fluorescence measurements were done by time-correlated single photon counting. The excitation pulse was provided by a Tsunami Ti:Sapphire laser (Spectra-Physics) which was pumped by a Millennia Pro X (Spectra-Physics). The Tsunami output was tuned between 920 nm and 1000 nm and subsequently frequency doubled to wavelengths between $460 \mathrm{~nm}-500 \mathrm{~nm}$. The emitted photons were collected by a thermoelectrically cooled micro-channel plate photomultiplier tube (R3809U-50, Hamamatsu). The signal was digitalized using a multichannel analyzer with 4096 channels (SPC-300, Edinburgh Analytical Instruments). The emission was collected at 780 nm for 4 and at 890 nm for $\mathbf{4 \cdot 3}, \mathbf{1 a \cdot 3}$ and 1a. The fluorescence decay curves were then fitted to either one or two-exponential expressions by the program FluoFit Pro v. 4 (PicoQuant GmbH). The time-resolved fluorescence decay curves are shown in Figure S . Fitted parameters are listed in Table S 1 where $\tau_{\mathbf{1}}$ represents the intrinsic fluorescence life time. 4 was fitted to a double-exponential model where the short life time corresponds to the previously observed conformational relaxation from twisted to planar conformation in the exited state of conjugated porphyrin oligomers. ${ }^{[1]}$ Due to overlapping fluorescence from an impurity (presumably an aggregated linear oligomer) and weak detector sensitivity above 850 nm , the fitting procedure of the circular hexamers where difficult and $\mathbf{4 . 3}$ and 1a could only be fitted using two exponentials where the short life time was attributed to the impurity emission.

Table S1. Fitted life times ( $\tau_{1}$ and $\tau_{2}$ ) and pre-exponential factors ( $a_{1}$ and $a_{2}$ ) from the fluorescence decays of $\mathbf{4}, \mathbf{4} \cdot \mathbf{3}, \mathbf{1} \mathbf{a} \cdot \mathbf{3}$ and $\mathbf{1 a}$ such as those plotted in Figure S1.

## Quantum Mechanical Calculations

The Gaussian 03 program suite ${ }^{[2]}$ was used for the quantum mechanical calculations. The five lowest electronic transitions of a linear, planar and a circular, butadiyne linked, porphyrin hexamer, similar to $\mathbf{1 a} / \mathbf{b}$ and $\mathbf{4}$ but without any substituents on the porphyrins, were computed using Time Dependent Density Functional Theory (TDDFT) with the B3LYP functional ${ }^{[3-5]}$ and the $6-31 \mathrm{G}(\mathrm{d})$ basis set. ${ }^{[6]}$ The structures were geometry optimized with PM3 prior to the TD-DFT calculation.

## Synthetic Procedures

All reagents were purchased from commercial sources. Manipulation of all air and/or water sensitive compounds was carried out using standard high vacuum techniques. Porphyrins, 2a/b, $\mathbf{7}$ and $\mathbf{8}$ were synthesized by adapting a published procedure. ${ }^{[7]}$

Column chromatography was carried out on Merck ${ }^{\circledR}$ silica gel 60 using a positive pressure of nitrogen. Where mixtures of solvents were used, ratios reported are by volume.
UV-visible spectra were recorded on a Perkin-Elmer Lambda 20 spectrometer. NMR spectra were recorded on Bruker instruments, DPX-400 or AV II-500 with cryoprobe. Chemical shifts are quoted as parts per million ( ppm ) relative to tetramethylsilane and coupling constants $(J)$ are quoted in Hertz (Hz). MALDI-TOF mass spectra were acquired by the EPSRC Mass Spectrometry Service, Swansea, UK. Computational chemistry was carried out using the MM+ force-field in HyperChem ${ }^{\text {TM }}$, Hypercube Inc. A correction factor of $4 \%$ was applied to compensate the underestimation of distances obtained by the molecular mechanics method. This correction factor was determined by comparison with X-ray crystal date for a range of closely related structures. UV-visible spectra were analyzed by fitting the experimental data to the theoretically expected curve using Origin ${ }^{\mathrm{TM}}$ or SPECFIT ${ }^{\mathrm{TM}}$ software. $^{\text {S }}$.

## Cyclic Octyloxy-Hexamer (1b)

Cyclic hexamer • template $\mathbf{1 b} .3(2.7 \mathrm{mg}, 0.36 \mu \mathrm{~mol})$ was passed through a size exclusion column (Biobeads SX-1) containing a ( $40 \mathrm{mg} \mathrm{mL}^{-1}$ ) solution of DABCO in toluene. The crude product mix was dissolved in chloroform and recrystallized by layer addition with methanol. The precipitate was isolated by passing the mix trough a 200 nm membranefilter to afford the template-free nanoring as a brownish solid ( $2.1 \mathrm{mg}, 89 \%$ ).

## Calculation of Equilibrium Constants

The curves in Figure S9 (b) and (d) were fitted with the following equations S1-S5, where M is either $\mathbf{1 b}$ or $\mathbf{4}, \mathbf{T}$ is hexadentate template $\mathbf{3}$, and $\mathbf{L}$ is either quinuclidine or pyridine.

$$
\begin{align*}
& K_{\mathrm{b}}=\left(\left[\mathbf{M} \cdot \mathbf{L}_{6}\right][\mathbf{T}]\right) /\left([\mathbf{M} \cdot \mathbf{T}][\mathbf{L}]^{6}\right)  \tag{S1}\\
& {[\mathbf{M}]_{0}=[\mathbf{M} \cdot \mathbf{T}]+\left[\mathbf{M} \cdot \mathbf{L}_{6}\right]}  \tag{S2}\\
& {[\mathbf{L}]_{0}=[\mathbf{L}]}  \tag{S3}\\
& {[\mathbf{T}]=[\mathbf{M} \cdot \mathbf{L} 6]}  \tag{S4}\\
& K_{\mathrm{b}}[\mathbf{M} \cdot \mathbf{T}][\mathbf{L}]_{0}{ }^{6}-\left([\mathbf{M}]_{O}-[\mathbf{M} \cdot \mathbf{T}]\right)^{2}=0 \tag{S5}
\end{align*}
$$

Equilibrium constants $K_{f}$ as occurring for the formation of $\mathbf{1 b} \mathbf{3}$ and $\mathbf{4 . 3}$ were evaluated by measuring how easily a competing ligand displaces the template ( $K_{\mathrm{b}}$ ), as shown by a thermodynamic cycle described in Equation S6. $K_{\mathrm{L}}$ is the binding constant of the competing ligand (quinuclidine or pyridine) for one zinc center of the porphyrin hexamer.

$$
\begin{equation*}
K_{\mathrm{f}}=K_{\mathrm{L}}{ }^{6} / K_{\mathrm{b}} \tag{S6}
\end{equation*}
