A. General Methods

Dry toluene was obtained by passing the solvent through a column of alumina, under nitrogen. Diisopropylamine (DIPA) was distilled from CaH₂ and kept over activated molecular sieves (3 Å, 8–12 mesh). Unless specified otherwise, all other solvents were used as commercially supplied.

Flash chromatography was carried out on silica gel 60 under positive pressure. Analytical thin-layer chromatography was carried out on aluminum-backed silica gel 60 F254 plates. Visualization was achieved using UV light when necessary. Gel-permeation chromatography (GPC) was performed on a line of JAIGEL 3H (20 × 600 mm) and JAIGEL 4H (20 × 600 mm) columns in the solvent of toluene/pyridine (100/1, v/v) and the flow rate of 3.5 mL/min. Analytical gel permeation chromatography (GPC) was performed on a JAIGEL H-P pre-column, a JAIGEL 3H-A (8 × 500 mm) and a JAIGEL 4H-A column (8 × 500 mm) in series with toluene/pyridine 100/1 as eluent or on two PLgel 3 µm Mixed-E columns (2 × 300 mm length, 7.5 mm diameter) and two PLgel 5 µm Mixed-D columns (3 × 300 mm length, 7.5 mm diameter) in series with THF as an eluent.

All UV-vis-NIR spectra were recorded in solution using a Perkin-Lambda 20 spectrometer (1 cm path length quartz cell). NMR data were collected on Bruker AVANCE AVIIIHD 400 and AVII 500 spectrometers. Samples were dissolved in dry CDCl₃ or CD₂Cl₂ and characterized by ¹H, COSY, edited-HSQC and ¹³C NMR and 2D NOESY spectra (with mixing times of 300 ms) using the standard Bruker pulse programs. Diffusion-edited spectra were collected using the standard Bruker pulse program, ledbp gp2s1d sequence for diffusion measurements using stimulated echo and LED (longitudinal eddy current delay) and bipolar gradient pulses for diffusion. With parameters big DELTA 100 ms, an eddy current delay of 5 ms and gradient strength 2–40% depending on the attenuation of solvent peaks. For each data set, 256 or 512 transients were acquired using recovery times of 3 s. Data were processed typically 32K data points using line broadening of 0.5 Hz.

¹H, ¹³C and ³¹P NMR spectra are reported in ppm; coupling constants are given in Hertz and are quoted to the nearest 0.1 Hz. Spectral referencing was based absolute spectrometer frequencies calculated relative to TMS scaling factors for the relevant nuclei, ¹H, ¹³C and ³¹P NMR ³¹P NMR spectra are referenced with respect to H₃PO₄ at 0 ppm.

ESI mass spectra were carried out either using Fisons Platform or Micromass LCT spectrometer. MALDI-TOF mass spectra were carried out using Waters MALDI Micro MX spectrometer.

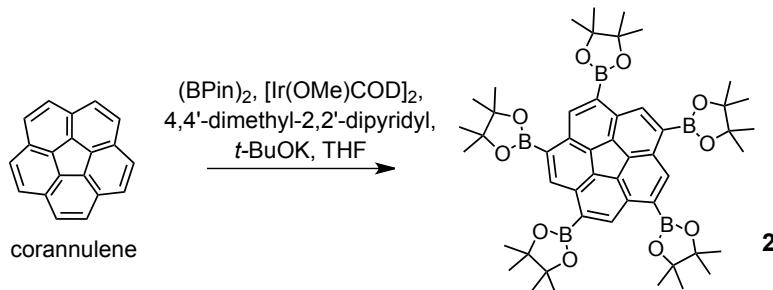

Steady-state absorption and time-integrated PL spectra at 298 K were recorded using a PerkinElmer Lambda 1050 UV-vis-NIR spectrometer and a Horiba FluoroLog fluorimeter respectively.

B. Synthetic Procedures

B1. Known Compounds

Di-*tert*-butyl-phosphinoferroocene tetrafluoroboric acid complex^{S1} (**1**, starting material for **T5_{Fc}**), pentakis-BPin corannulene^{S2} (**2**, starting material for **T5_{cor}**) and porphyrin monomers **P1**^{S3, S4} were synthesized using published procedures. Our slightly modified procedure for preparation of pentakis-BPin corannulene (**2**) is detailed here:

Pentakis-BPin corannulene, **2**

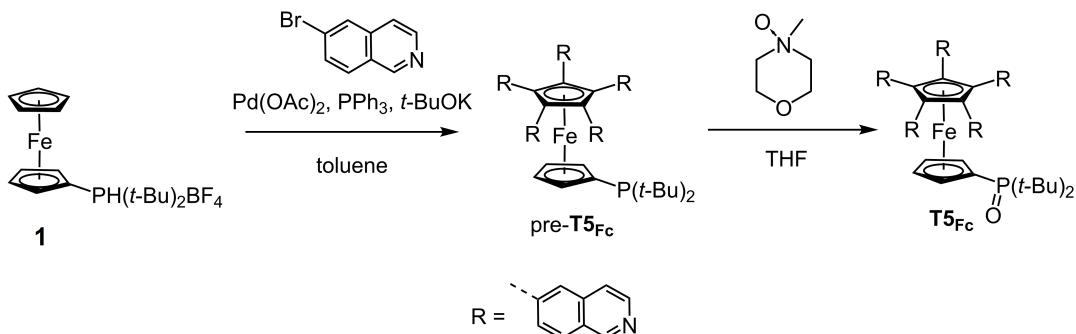

Scheme S1. The synthesis of pentakis-BPin corannulene **2**

A pressure vessel was charged with $[\text{Ir}(\text{OMe})\text{COD}]_2$ (53 mg, 0.08 mmol), 4,4'-dimethyl-2,2'-dipyridyl (30 mg, 0.16 mmol), $(\text{BPin})_2$ (528 mg, 2.08 mmol) and *t*-BuOK (5 mg, 0.04 mmol), all as dry solids. THF (0.4 mL) was added by syringe and the mixture was heated at 50 °C for 5 min under N₂. A dark brown-red solution formed. The vessel was charged with corannulene (100 mg, 0.40 mmol), purged with N₂, sealed and stirred at 85 °C for 4 days. The reaction mixture was cooled, opened to the air and immediately diluted with DCM (5 mL), then quenched by dropwise addition of water (3 mL). The layers were separated and the aqueous layer was thoroughly extracted with DCM. The combined organic layers were washed with water and brine, and dried over magnesium sulfate. The filtrate was concentrated to dryness on a rotary evaporator to give a dark red-brown oily mixture. Methanol (8 mL) was added and the mixture was sonicated for 10 min, until the dark mixture separated into a dark solution and an off-white precipitate. The precipitate was collected by vacuum filtration and washed with methanol to yield **2** as white solid (192 mg, 55%).

B2. Novel Compounds

T5_{Fe}

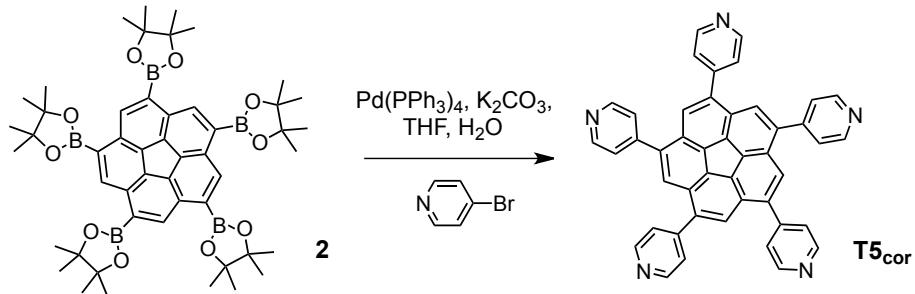

Scheme S2. The synthesis of T5_{Fc}

Compound **1** (0.12 g, 0.28 mmol), 6-bromoisoquinoline (0.70 g, 3.3 mmol), *t*-BuOK (0.30 g, 2.6 mmol), Pd(OAc)₂ (6.0 mg, 0.027 mmol) and PPh₃ (33 mg, 0.13 mmol) were dissolved in dry toluene (12 mL). The mixture was degassed using the freeze-pump-thaw method and was then stirred vigorously at 107 °C under argon for 2 days. The mixture was cooled and filtered through Celite and the solvent was evaporated under vacuum. The residue was separated with column chromatography (SiO₂) using DCM/EtOH (80/11 gradually increasing polarity to 5/1, *v/v*) as the eluent. Pre-**T5Fc** was obtained as the last dark red band (0.11 g, 40%). pre-**T5Fc**: ¹H NMR (400 MHz, CDCl₃): δ = 9.19 (s, br, 5H), 8.43 (s, br, 5H), 7.69 (s, 5H), 7.65 (d, *J* = 8.5 Hz, 5H), 7.45 (dd, *J* = 8.5 Hz, *J* = 1.0 Hz, 5H), 7.26 – 7.24 (m, 5H), 4.78 (s, 2H), 4.64 (t, *J* = 1.6 Hz, 2H), 1.04 (d, *J* = 11.2 Hz, 18H); ¹³C NMR (100 MHz, CDCl₃): δ = 152.2, 143.6, 137.4, 135.0, 131.8, 130.0, 126.5, 88.1, 78.4, 78.3, 76.6, 33.6 (d, *J* = 25 Hz), 31.1 (d, *J* = 13 Hz); ³¹P{¹H} NMR (CDCl₃, 162 MHz): δ = 24.91.

C2. Characterization of *c*-P5·T5_{Fe}

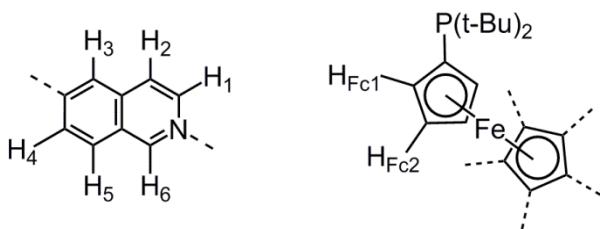

Figure S25. Designation of the protons in T5_{Fe}.

The chemical shifts of the protons on porphyrin structure *c*-P5·T5_{Fe} are similar to those reported for *c*-P6·T6.⁵⁵ The major task is to assign the protons in the template: isoquinoline unit, cyclopentadiene unit and *tert*-butyl unit.

We can start the identification process from the HSQC spectrum. The correlation signals of the 6 protons on the isoquinoline structure are in the range between 120 ppm and 145 ppm, which is the range of aromatic carbons. H1 and H6 can be identified by the chemical shifts of the carbon atoms that they attach to; the assignment of other protons on the isoquinoline unit, HFc₁ and HFc₂ will be shown in following figures.

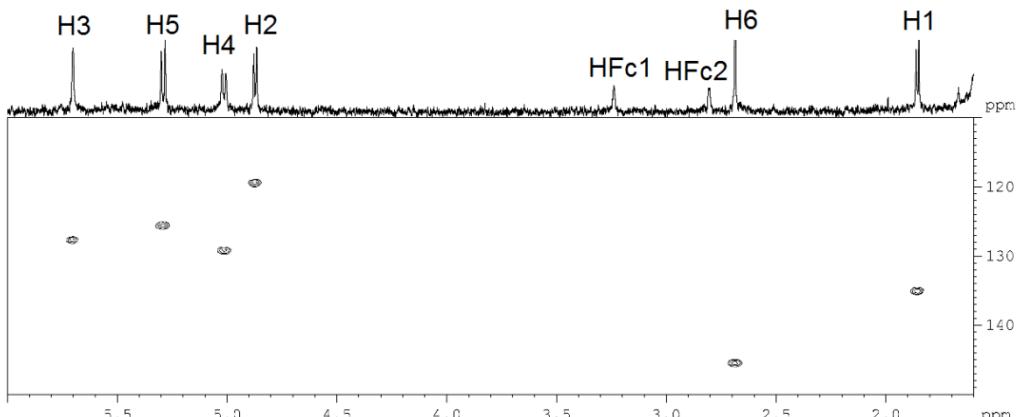

Figure S26. Identification of six isoquinoline protons from ¹H-¹³C HSQC spectrum (diffusion-edited ¹H spectrum projection of *c*-P5·T5_{Fe}, CD₂Cl₂, 500 MHz, 298 K). HFc₁ and HFc₂ don't have correlation signals in this figure since the carbon atoms that they attach to have the chemical shifts in the range between 75 and 80 ppm.

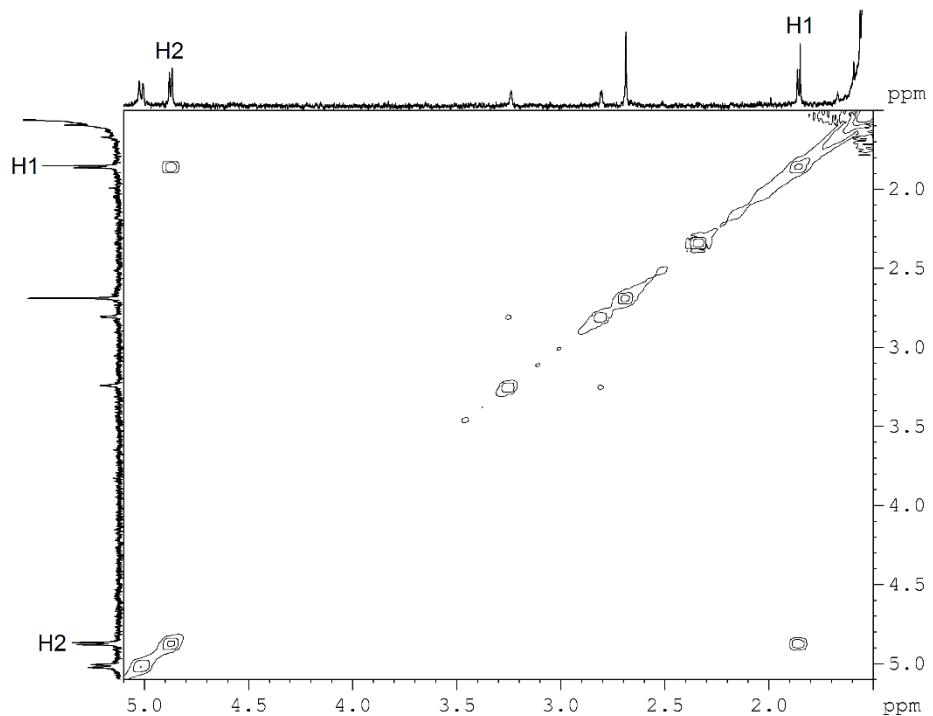

Figure S27. Correlation signal of $H_1 - H_2$ in ^1H - ^1H COSY spectrum (diffusion-edited ^1H spectrum projection, CD_2Cl_2 , 500 MHz, 298 K).

As is shown in **Figure S27**, assignment of the isoquinoline peaks starts from a COSY peak between H_1 (1.86 ppm) and H_2 (4.87 ppm). The peak of H_1 at 1.86 ppm is typical of the most shielded protons in the template.

As is shown in **Figure S28**, H_2 has strong NOE signals with H_1 and H_3 (5.70 ppm).

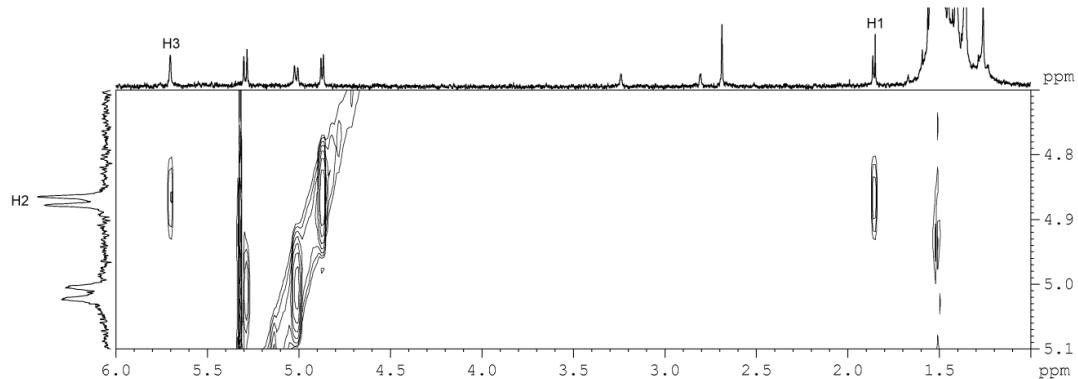

Figure S28. Correlation signals of $H_1 - H_2$ and $H_3 - H_2$ in ^1H - ^1H NOESY spectrum (diffusion-edited ^1H spectrum projection of $c\text{-P5}\cdot\text{T5}_{\text{Fc}}$, CD_2Cl_2 , 500 MHz, 298 K).

As is shown in **Figure S29**, H_3 has NOE signals with H_2 (strong) and H_4 (5.01 ppm, weak).

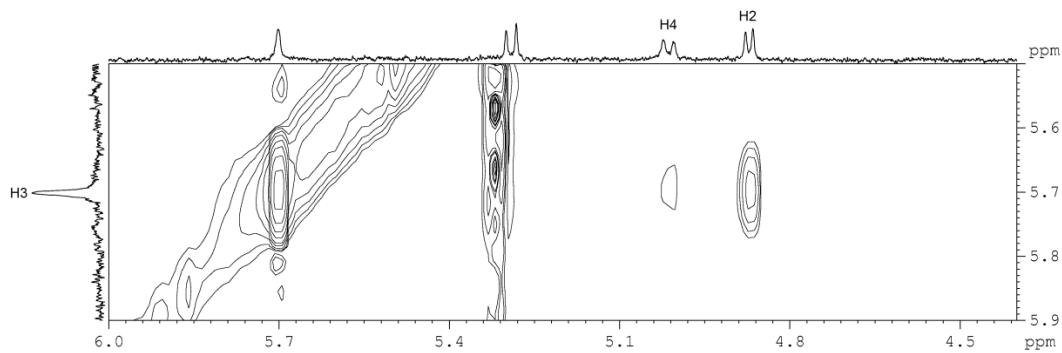

Figure S29. Correlation signals of H_3 - H_4 and H_3 - H_2 in ^1H - ^1H NOESY spectrum (diffusion-edited ^1H spectrum projection of *c*-P5·T5Fc, CD_2Cl_2 , 500 MHz, 298 K).

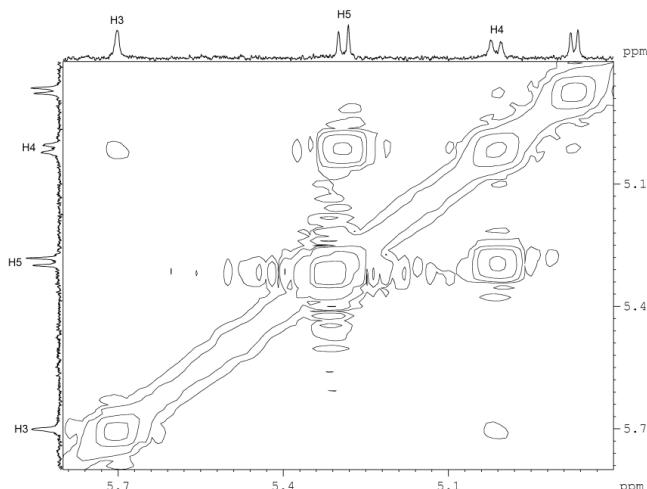

Figure S30. Correlation signal of H_4 - H_5 and H_4 - H_3 in ^1H - ^1H COSY spectrum (diffusion-edited ^1H spectrum projection of *c*-P5·T5Fc, CD_2Cl_2 , 500 MHz, 298 K).

As is shown in **Figure S30**, H_4 has COSY signals with H_5 (5.30 ppm, strong) and H_3 (weak).

As is shown in **Figure S31**, H_5 has NOE signals with H_4 and H_6 (2.69 ppm). H_6 is a singlet and has no COSY signals with other 5 protons on the isoquinoline structure.

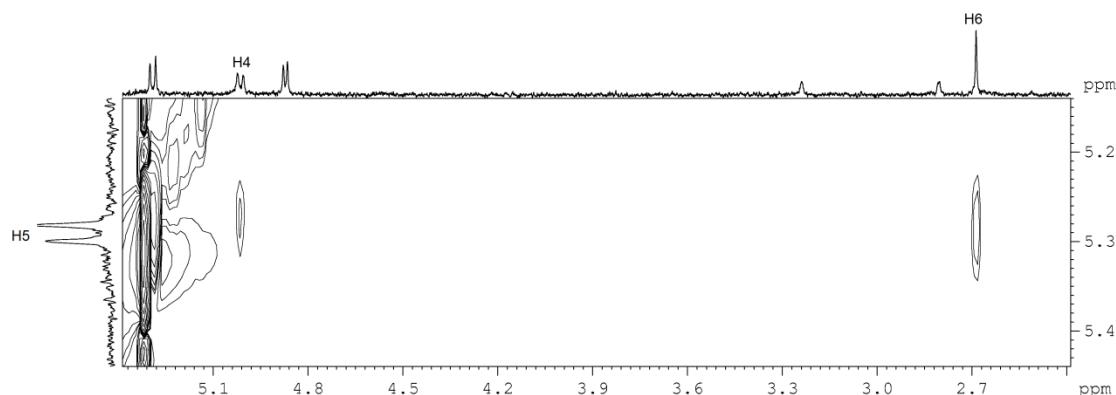

Figure S31. Correlation signals of H_5 - H_4 and H_5 - H_6 in ^1H - ^1H NOESY spectrum (diffusion-edited ^1H spectrum projection of *c*-P5·T5Fc, CD_2Cl_2 , 500 MHz, 298 K).

As shown in **Figure S32**, the peaks at 3.24 ppm and 2.80 ppm belong to ferrocene protons, which have various NOE signals with isoquinoline protons. The *tert*-butyl protons (-0.25 ppm) on the ferrocene phosphine structure have NOE signals with H_{Fc1} (3.24 ppm); yet they do not have NOE signals with H_{Fc2} (2.80 ppm), which has longer distance in between them. Both H_{Fc1} and H_{Fc2} have NOE signals to H₃ and H₄, which are the isoquinoline protons close to the ferrocene core.

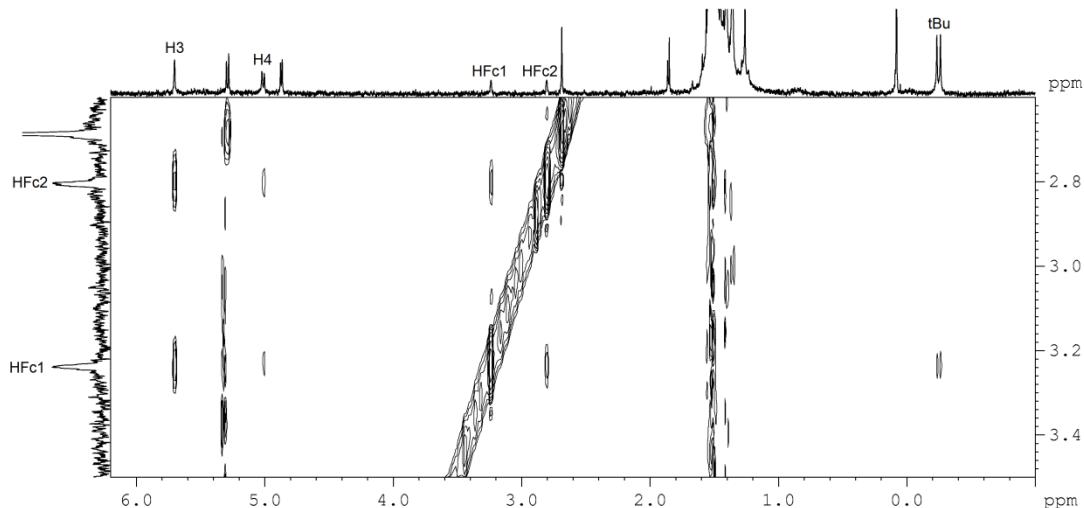

Figure S32. Correlation signals of H_{Fc1} - H₃, H_{Fc1} - H₄, H_{Fc1} - H_{t-Bu}, H_{Fc2} - H₃, H_{Fc2} - H₄ and H_{Fc1} - H_{Fc2} in ¹H-¹H NOESY spectrum (diffusion-edited ¹H spectrum projection of **c-P5-T5_{Fe}**, CD₂Cl₂, 500 MHz, 298 K).

H₁ and H₆, which are the closest protons (in the template) to the porphyrins, has NOE signals with the beta- and only one (the one facing towards the inner side of the porphyrin ring structure) of the six aryl protons in the porphyrin.

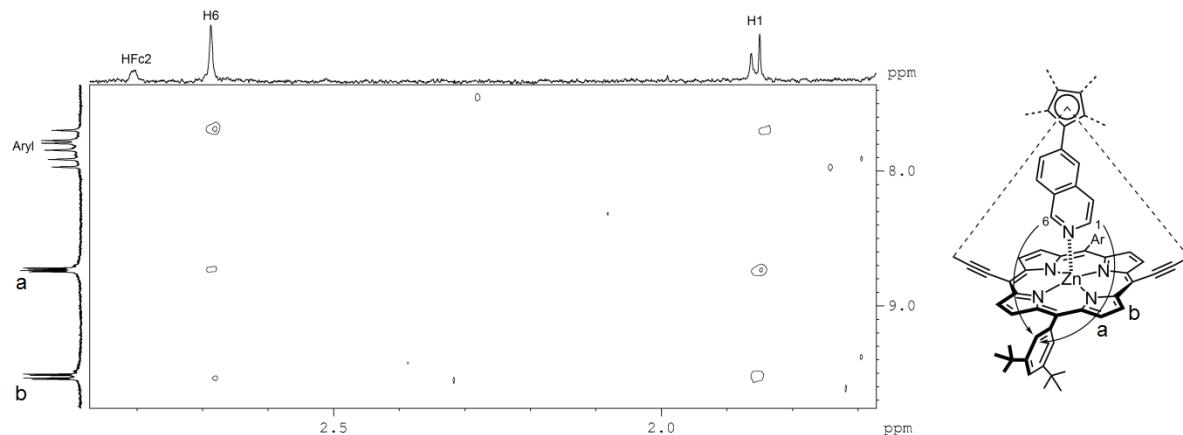

Figure S33. Correlation signals of H₁ and H₆ with the beta and only one of the six aryl-protons in ¹H-¹H NOESY spectrum (diffusion-edited ¹H spectrum projection of **c-P5-T5_{Fe}**, CD₂Cl₂, 500 MHz, 298 K).

C3. Characterization of *c*-P5_{Oct}·T5_{Fc}

c-P5_{Oct}·T5_{Fc} has a very similar spectrum to *c*-P5·T5_{Fc}. Two doublets from beta-protons overlap with each other and a doublet appear at 8.80 ppm. More signals appear from the alkyl chains on the porphyrin: H₁ is overlapped under one of the alkyl chain signals at around 1.8 ppm. The ¹H-¹³C COSY, ¹H-¹H COSY and ¹H-¹H NOESY spectra all give evidences for the overlap.

C4. Characterization of *c-P5·T5_{cor}*

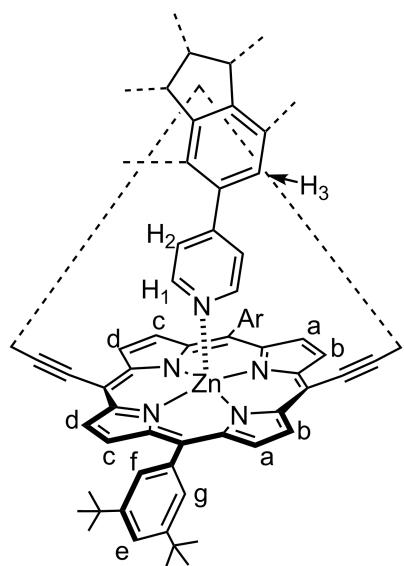

Figure S38. Designation of the protons in *c*-P5·T5_{cor}.

Compared to $c\text{-P5}\cdot\text{T5}_{\text{Fc}}$, $c\text{-P5}\cdot\text{T5}_{\text{cor}}$ has a simpler template structure, which makes the designation of template signals easier.

C5. The Shielding Effects of Porphyrin Nanoring

As is shown below, the shielding effect of the porphyrin nanoring can be reflected by the change of chemical shifts of the template protons between the free form and the nanoring-bound form.

D. Fluorescent Properties

D1. Time-Resolved Photoluminescence Spectroscopy

To investigate photoluminescent (PL) decay dynamics, electronic gating through the time-correlated single-photon counting (TCSPC) technique was used (Becker & Hickl module). Here, the emission was detected with a silicon single-photon avalanche diode, yielding a temporal resolution of around 40 ps. By fitting the PL intensity (I) decay to a single exponential decay model, $I = Ae^{-t/\tau}$, the lifetime τ of the emission was extracted.

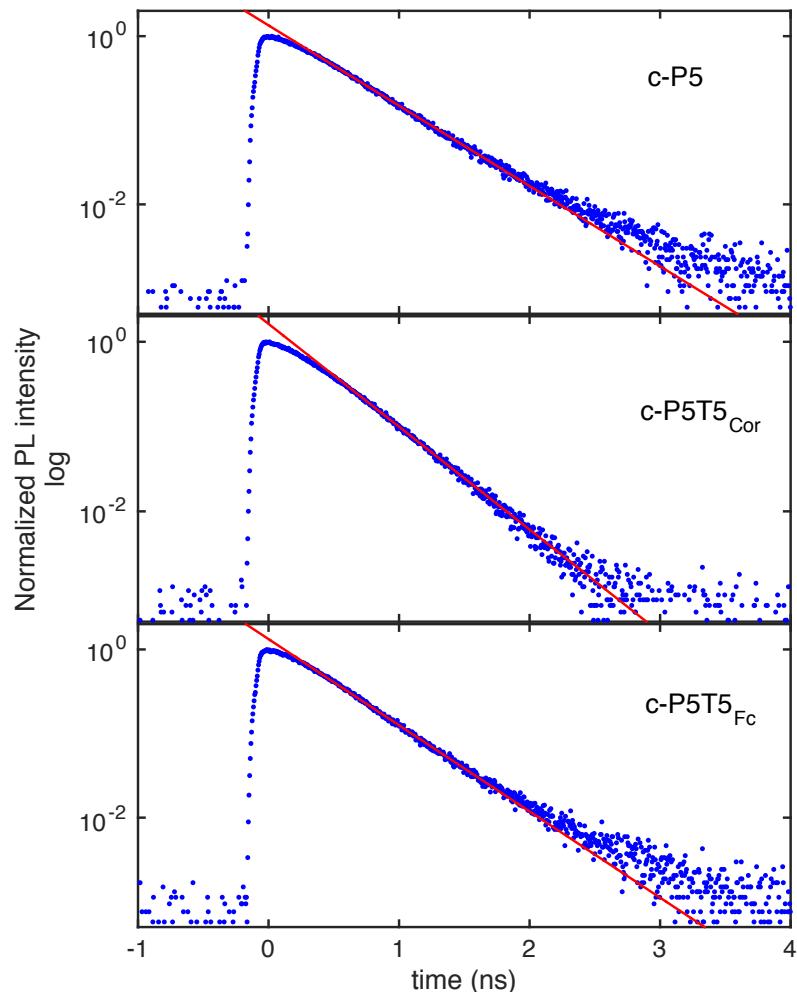

Figure S46. Normalized PL intensity decay dynamics of 5-porphyrin nanorings on log scale (blue) and single exponential fit to the intensity decay (red) recorded using TCSPC in toluene/1% pyridine solution at 450 nm excitation.

D2. Quantum Yield and Radiative Rates

As quantum yield (QY) measurements had been carried out on porphyrin nanorings in previous studies,^{S6} a relative approach was adopted in this study using **I-P6** (see the reference for the compound structure) as a reference:

$$QY_{sample} = \frac{I_{sample}}{I_{ref}} \times \frac{Abs_{ref}(\lambda_{ext})}{Abs_{sample}(\lambda_{ext})} \times QY_{ref} \quad (S.1)$$

where I is the integrated area of PL emission spectrum at the excitation wavelength λ_{ext} and $Abs(\lambda_{ext})$ is the absorbance at λ_{ext} . The QY of the reference compound **I-P6** is 28%.

Using the obtained quantum yield and the overall decay rate Γ_{total} extracted from the PL transients ($\Gamma_{total} = 1/\tau$), the radiative (Γ_{rad}) and non-radiative (Γ_{nr}) rate were extracted using: $\Gamma_{rad} = QY \times \Gamma_{total}$ and $\Gamma_{total} = \Gamma_{rad} + \Gamma_{nr}$.

E. Effective Molarity Measurement

E1. Titrations of Monodentate Ligands with **c-P5** (Reference Titrations)

c-P5 was titrated with monodentate ligands (quinuclidine, pyridine and isoquinoline) to measure their association constants.

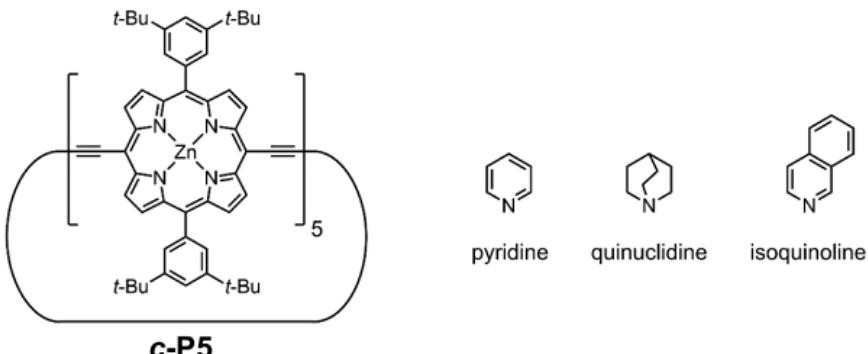

Figure S47. Ligands used for measurements of reference association constants of **c-P5**.

All the titrations were performed in toluene at 298 K and the concentration of porphyrin nanorings was 1.5 μ M. All titrations were carried out at constant porphyrin concentration by adding porphyrin to the ligand stock solution before starting the titrations. Titration curves were fitted to a 1:1 binding isotherm using the equation:

$$\frac{A - A_{initial}}{A_{\infty} - A_{initial}} = \left(\frac{(K_a([L] + [P]_0) + 1) - \sqrt{(K_a([L] + [P]_0) + 1)^2 - 4K_a^2[P]_0[L]}}{2K_a[P]_0} \right) \quad (\text{S.2})$$

where A is the observed absorption at a specific wavelength; $A_{initial}$ is the starting absorption at this wavelength; A_{∞} is the asymptotic final absorption at this wavelength; K_a is the association constant between ligand and porphyrin host; $[L]$ is the total (free and bound) concentration of ligand; $[P]_0$ is $5 \times [\text{c-P5}]$ (concentration of **c-P5**). The difference between absorptions at two different wavelengths can be substituted for each of the absorption parameters (A , $A_{initial}$, A_{∞}).

The results are listed in **Table S2** and figures below. In the stacked spectra, the bold black lines represent starting points and the red lines represent terminal points.

All the titrations were performed in toluene at 298 K. All titrations were carried out at constant porphyrin nanoring concentration by adding porphyrin to the ligand stock solution before starting the titrations. All the data were fitted to the *n*-dentate breaking-up binding isotherm shown as below:

$$\frac{A - A_{initial}}{A_\infty - A_{initial}} = \left(\frac{-K_d[L]^n + \sqrt{K_d^2[L]^{2n} + 4K_d[L]^n[P]_0}}{2[P]_0} \right) \quad (\text{S.3})$$

where A is the observed absorption at a specific wavelength; $A_{initial}$ is the starting absorption at a specific wavelength; A_∞ is the terminal absorption at a specific wavelength; K_d is the dissociation constant between ligand and porphyrin nanoring complex; $[L]$ is the concentration of ligand; $[P]_0$ is the concentration of porphyrin nanoring complex; n is the number of binding sites of nanoring complexes. For **c-P5·T5**, $n = 5$. The difference between absorptions at two different wavelengths can be substituted for each of the absorption parameters ($A, A_{initial}, A_\infty$).

E4. Calculation of Effective Molarities

The formation constants K_f of **c-P5·T5_{Fc}** and **c-P5·T5_{cor}** were calculated from equation (S.4):

$$\log K_f = \log \frac{K_L^n}{K_{d,L}} = n \log K_L - \log K_{d,L} \quad (\text{S.4})$$

where K_L is the association constants of the template-free ring with ligand L; $K_{d,L}$ is the denaturation constants of the nanoring-template complex with this ligand; n is the chelation number of nanoring-template complexes. For **c-P5·T5**, $n = 5$. The uncertainty in $\log K_f$ was calculated from equation (S.5):

$$\Delta(\log K_f) = \frac{1}{\ln 10} \sqrt{\left(\frac{n \Delta K_L}{K_L} \right)^2 + \left(\frac{\Delta K_{d,L}}{K_{d,L}} \right)^2} \quad (\text{S.5})$$

where ΔK_L is the uncertainty of K_L and $\Delta K_{d,L}$ is the uncertainty of $K_{d,L}$.

The resulting values of $\log K_f$ are listed in **Table S5**:

Table S5. Formation constants of nanoring-template complexes (logarithms are decadic).

Nanoring	Denaturation ligand	Calculated $\log K_f$
c-P5·T5_{Fc}	quinuclidine	29.3 ± 0.2
c-P5·T5_{Fc}	pyridine	29.1 ± 0.1
c-P5·T5_{cor}	pyridine	28.5 ± 0.1

The geometric average effective molarities (\overline{EM}) of the nanoring complexes were calculated from equation (S.6):

$$\log \overline{EM} = \log \sqrt[n-1]{\frac{K_{\text{chem},n}}{K_1^n}} = \log \sqrt[n-1]{\frac{K_f}{K_\sigma K_1^n}} = \frac{(\log K_f - \log K_\sigma - n \log K_1)}{(n-1)} \quad (\text{S.6})$$

where $K_{\text{chem},n}$ is the statistically corrected value of K_f . As is shown in **Figure S60**, for both **c-P5·T5_{Fc}** and **c-P5·T5_{cor}**, $K_\sigma = 320$. K_1 is the reference single-site microscopic binding constant statistically corrected for binding to one face of a porphyrin (i.e. $K_1 = 0.5K_{\text{iso}}$, half of the binding constants measured in reference association titrations in **Section E1**). The uncertainties in the values of $\log \overline{EM}$ were calculated from equation (S.7):

$$\Delta(\log EM) = \frac{1}{(n-1)} \sqrt{(\Delta(\log K_f))^2 + \left(\frac{n \Delta K_1}{\ln 10 K_1} \right)^2} \quad (\text{S.7})$$

The geometric average effective molarities of the nanoring complexes are listed in **Table S6**:

F. Computational details

Molecular models were built in HyperChem v. 7.0 using the MM+ forcefield with parameters modified for the description of porphyrins.^{S7} The porphyrin *meso* aryl groups were replaced with H, as was the di-*tert*-butyl phosphine oxide moiety on **T5_{Fc}**. The Polak-Ribiere and steepest descent algorithms were used for geometry optimizations. A twisted and planar conformation of each of **c-P5•T5_{cor}** and **c-P5•T5_{Fc}** were prepared in HyperChem. The resulting geometries were subjected to further optimization in MOPAC2016 using the PM6 level of theory, and in the absence of symmetry.^{S8} The eigenvector following minimization routine was used for the geometry optimization. For **c-P5•T5_{cor}** the conformation of the starting HyperChem geometry (twisted or planar) was retained in the PM6-optimized structure. Both twisted and planar PM6 structures had no negative frequencies in force calculations. In contrast, both starting **c-P5•T5_{Fc}** structures converged to similar geometries.

DFT geometry optimizations were performed using Gaussian 09/D.01 with the B3LYP functional and the 6-31G* basis set and an empirical dispersion correction recommended by Grimme (GD3).^{S9}

For **c-P5•T5_{cor}**, both twisted and planar PM6 geometries were used as starting points, the latter in C_5 symmetry. With DFT, both starting structures ultimately converged to similar twisted structures, with C_1 symmetry. Correspondingly, the geometry optimization from the twisted PM6 guess was remarkably quick (299 CPU hours) compared to the C_5 symmetric planar PM6 guess (892 CPU hours).^{S10} The lower energy of the two DFT structures ($\Delta E = 2 \text{ kJ mol}^{-1}$) was subjected to a frequency calculation (666 CPU hours), revealing no imaginary frequencies.

For **c-P5•T5_{Fc}**, the MOPAC geometry was similarly used as a starting point for DFT geometry optimization (1211 CPU hours). The frequency calculation on **c-P5•T5_{Fc}** revealed a very small imaginary mode (1.1 cm^{-1}), to which we attribute no significance.

The free templates **T5_{cor}** and **T5_{Fc}** were optimized by DFT (B3LYP/6-31G* level of theory), each in C_5 symmetry, following pre-optimization of a HyperChem model in MOPAC by PM6. Frequency calculations confirmed the minimum nature of the stationary point, with no imaginary frequencies.

Key structural parameters are reproduced in Table S7. r_N and r_{Zn} refer to the radii of the N-donor and Zn-acceptor sets of the molecules. oop_{Zn} (out of plane) refers to the root mean squared (RMS) deviation of the Zn atoms in the complex from coplanarity.

Coordinates of optimized geometries and final SCF energies are given in xyz files in the SI .ZIP file.

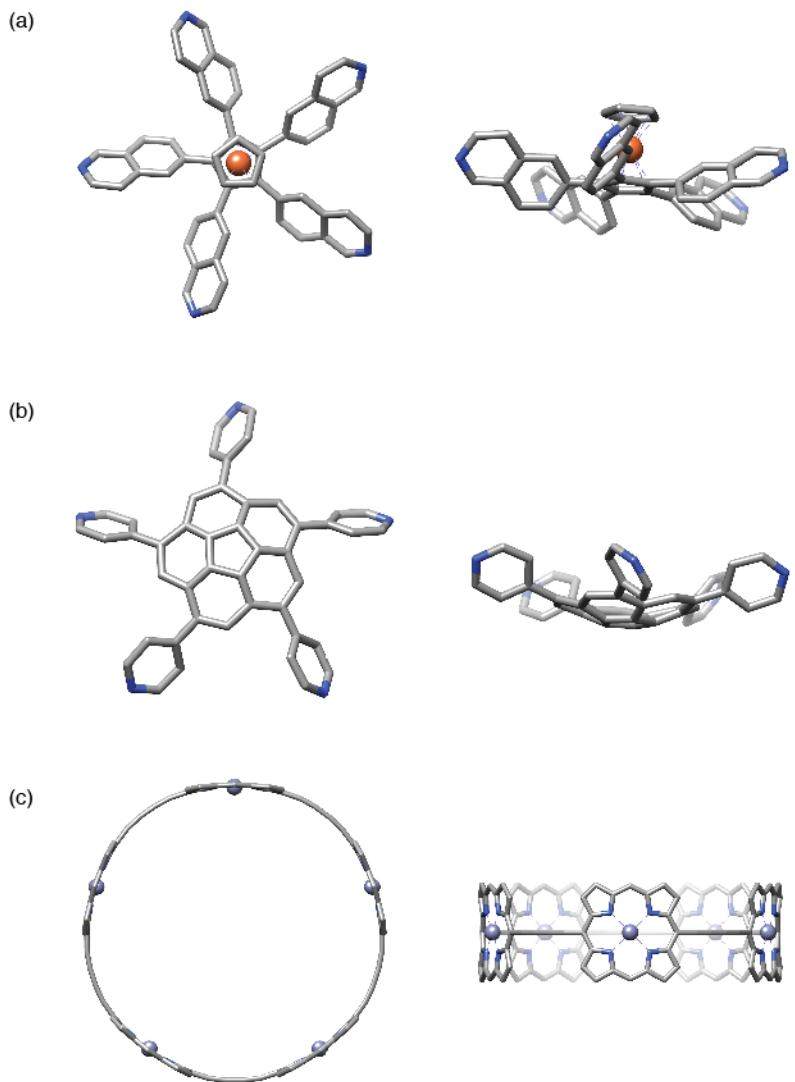

Figure S61. Geometry optimized DFT (B3LYP/6-31G*, GD3) structures for (a) $\mathbf{T5}_{\text{Fe}}$, (b) $\mathbf{T5}_{\text{cor}}$ and (c) $\mathbf{c\text{-}P5}$ (aryl groups truncated to $-\text{H}$).

The strain energy in $\mathbf{c\text{-}P5}$ was estimated by a homodesmotic reaction (Figure S62 and Table S8) at the B3LYP/6-31G* level of theory, using the D3 dispersion correction.

A post-hoc correction with Grimme's gCP-D3(BJ) method,^{S11} applied to B3LYP/6-31G* geometries calculated without iterant application of the D3 correction, did not significantly affect the result.

Similarly, the strain energy was not significantly changed when we used diphenylbutadiyne ($\text{Ph-C}\equiv\text{C-C}\equiv\text{C-Ph}$) in place of $\mathbf{I\text{-}P2}$ and the corresponding phenylacetylene capped $\mathbf{I\text{-}P5}$ in place of $\mathbf{I\text{-}P7}$ (in Figure S62).
